“Does Matching Student and Teacher Racial/Ethnic
Group Improve Math Scores?”

By:

Stephen Klein, Vi-Nhuan Le, and Laura Hamilton

Abstract

We investigated whether students earn higher math test scores when they have a teacher whose racial/ethnic group is the same as their own. Using data from fourth-grade teachers and students in California, we computed individual-level regression equations that controlled for district differences and variations in teacher and student background characteristics. After adjusting for several student and teacher characteristics, only teaching experience showed a statistically significant correlation with student test scores. The other teacher characteristics we measured, including racial/ethnic group, did *not* tend to be related to student achievement. However, the pattern of coefficients lend some support to the hypothesis that white and other students score higher when they have teachers whose racial/ethnic group is the same as their own. In contrast, Hispanic and black examinees did not earn higher scores when they had teachers whose racial/ethnic group was the same as their own.

About two million new teachers will be needed in the next decade (National Commission on Teaching and America's Future, 1997). This demand stems from several factors, including increasing student enrollments (especially for minority groups), the trend toward smaller class sizes, and anticipated teacher retirements. Nevertheless, many states appear to be curtailing the supply of teachers as a result of their requiring more rigorous certification standards (Darling-Hammond, 2000). These higher standards—which are usually adopted in the hopes of improving the quality of teaching—often have an adverse impact on minority candidates (Cole, 1986; Ferguson, 1991). For example, the first-time passing rates of white, Asian, Hispanic, and black candidates on the basic skills test that California requires for all teachers were 80%, 60%, 47%, and 37%, respectively (Orrick, 1996). The same pattern holds in other states (Kirby et al., 1999).

These disparities in passing rates are particularly troubling to those who have striven to increase the presence of minority teachers in schools. One argument that is offered to support a greater presence is that minority teachers are generally more effective than white teachers with minority students. However, there is very limited empirical support for this thesis. For example, in a reanalysis of 1966 data from the *Equality of Educational Opportunity* study, Ehrenberg and Brewer (1995) found that after controlling for various teacher, school, and student characteristics, black high school students gained more when a higher percentage of their teachers were black. Studying the achievement of black elementary students, Murnane (1975) found that gains in math and reading were a quarter to one-half standard deviation higher with black teachers than with white teachers. In contrast, using data from the National Education Longitudinal Study of 1988, Ehrenberg, Goldhaber, and Brewer (1995) found that black and white teachers were equally effective with black students. Similarly, Alexander, Entwisle, and Thompson (1987) reported that black students in Baltimore performed equally well with black and white teachers. However, student scores and race interacted with their teacher's socioeconomic status (SES) and race. Low-SES black teachers were most effective in increasing black students' scores, whereas high-SES black teachers were the least effective.

Studies of the effect of the match between student and teacher racial/ethnic group on student test scores have been fraught with several serious limitations. For example, test scores from only one year were available in the *Equality of Educational Opportunity* data. Thus, Ehrenberg and Brewer could not control for prior achievement (and their study was based on data collected 35 years ago). Most of the prior studies have used the school (rather than the classroom) as the unit of analysis. Thus, they could not control for the racial/ethnic group of the student's own teacher, and their results are highly susceptible to aggregation bias.

Purpose

The study described below used data on fourth graders to examine the hypothesis that students earn higher math scores when they have a teacher whose racial/ethnic group is the same as their own. For example, all other things being equal, do black students receive higher scores if they have a black teacher than if they have a white or Hispanic or Asian teacher? We also explored whether student scores are related to their teacher's certification level and training in mathematics.

Methodology

We collected student and teacher information at a sample of 136 California elementary schools. These schools are in 11 districts that together contain about 20% of all the students in the state. The 281 fourth-grade teachers who participated in this study completed a survey that gathered data on their gender, racial/ethnic group, certification, highest degree received, coursework in mathematics, and years of teaching experience. For the 18 percent of students who were missing at least one prior year's test scores, we imputed values using student and teacher background variables.

To examine whether students do better if they have the same racial/ethnic group as their teachers, we computed individual-level regression equations that controlled for district differences and variations in teacher and student characteristics. For teachers, we controlled for gender, certification type, degree, mathematics coursework, and total years teaching. For students, we controlled for prior year math and reading scores, gender, home language, and whether the student participated in a gifted program, a special education program, and/or a free or reduced price lunch program. The dependent variable was 1999 Stanford 9 math scores. Standard errors were adjusted for the clustering of students within classrooms.

Results

Table 1 shows the distribution of teacher qualifications by teacher racial/ethnic group. In comparison to white teachers, black and Hispanic teachers had less teaching experience. However, black teachers were more likely to have a masters degree than were white teachers, and Hispanic teachers had slightly more math coursework than white teachers. White teachers were similar to "other" teachers with respect to credentials and years teaching, but white teachers had taken fewer math courses and were less likely to hold a higher degree.

Table 1
Distribution of Teacher Qualifications by Teacher Racial/Ethnic Group

Teacher's R/E Group	Percent with a				Average Number of	
	Math Credential	General Credential	No Credential	Masters Degree	Math Courses Taken	Years Teaching
White	4.6	91.9	8.1	32.5	4.2	3.2
Hispanic	6.3	65.6	34.4	34.4	5.2	2.5
Black	0	72.2	27.8	61.1	3.7	2.4
Other	0	88.2	11.8	55.9	5.5	2.9
Total	3.9	87.2	12.8	37.4	4.4	3.0

Note. Credential columns do not add to 100% because math credentials are a subset of general credentials.

Table 2 shows the number of teachers and students in each racial/ethnic group. The majority of the teachers were white, but most students were not. Table 3 shows that teachers were somewhat more likely to have students whose racial/ethnic group was the same as their own. This was particularly true of Hispanic teachers, who taught an average of 14 Hispanic students per class of 21 total students.

Table 2
Number of Students and Teachers by Racial/Ethnic (R/E) Group

Teacher's R/E Group	Student's R/E Group				Total
	White	Hispanic	Black	Other	
White (197)	2159	1398	493	862	4912
Hispanic (32)	128	452	40	43	663
Black (18)	64	142	147	54	407
Other (34)	206	270	78	279	833
Total (281)	2557	2262	758	1238	6815
% of all students	38%	33%	11%	18%	100%

Notes. Columns and rows correspond to students and teachers, respectively. The cells show the number of students taught. The number of teachers in each racial/ethnic group is shown in parenthesis. Most of the "others" are Asians.

Table 3
Average Number of Students Per Teacher as a Function of the Teacher's and Student's Racial/Ethnic (R/E) Group

Teacher's R/E Group	Student's R/E Group				Total
	White	Hispanic	Black	Other	
White	11	7	3	4	24.9
Hispanic	4	14	1	1	20.7
Black	4	8	8	3	22.6
Other	6	8	2	8	24.5

Note. Row totals differ from the sum of the cells in a row due to rounding.

We constructed two sets of regression analyses with four equations per set. One set contained a dummy variable for whether the student's teacher was white or not. The other set contained three dummy variables per equation corresponding to whether the student's teacher was black, Hispanic, or other non-white. Within each set we constructed separate equations for white, black, Hispanic, and other students. Thus, we constructed a total of eight equations.

Table 4 shows the R^2 values for equations with and without teacher race. Including teacher race in the regression model resulted in virtually no increase in R^2 ,

which suggests that at best, teacher race bears only a weak relationship to student achievement.

Table 4
R² Values for Regression Models With and Without Teacher Race

Regression Model	Student's R/E Group			
	White	Hispanic	Black	Other
Teacher race excluded	.646	.633	.651	.720
Dummy variable for white versus non-white teacher	.647	.633	.654	.720
Dummy variable for minority teachers	.647	.634	.653	.722

Table 5 shows the effect sizes of teacher race on student achievement for each combination of student and teacher racial/ethnic group. There was some evidence that minority teachers were, on average, less effective than white teachers. Black students performed significantly better with white teachers than with minority teachers. Although the result was not statistically significant, white students also scored higher with white teachers than teachers of another race. Hispanic examinees tended to score lower with "other" and black teachers, but Hispanic teachers were as effective as white teachers in teaching Hispanic students. "Other" students performed better with "other" and Hispanic teachers than with white teachers. However, "other" examinees with black teachers scored lower than "other" examinees with white instructors.

Table 5
Effect Size of Teacher Race on Student Achievement

Teacher's R/E Group	Student's R/E Group			
	White	Hispanic	Black	Other
White	.104	.019	.124 *	-.036
Hispanic	-.051	.018	-.170	.055
Black	-.127	-.090	-.098	-.175
Other	-.094	-.037	-.148	.093

Notes. Minority teachers serve as the reference group for the first row. White teachers serve as the reference group for the last three rows.

* Significant at .05 level.

Appendix A shows the eight regression equations. These data indicate that after controlling on other factors, participation in a gifted program was positively related to scores in every racial/ethnic group except blacks. Similarly, black females scored significantly higher than black males, but there were no gender differences within any of the other racial/ethnic groups. Within whites, special education examinees demonstrated poorer performance than non-special education examinees, but special education students of another race/ethnicity performed as well as their counterparts.

Teaching experience was the only teacher variable that was significantly correlated with student achievement across all students' racial/ethnic groups. General credentials were positively related to outcomes for white students, but were unassociated with scores for examinees of another race/ethnicity. Other teacher characteristics studied (gender, degree, math credentials, and math coursework) were also unrelated to student performance.

Because there were few teachers in some cells, the small sample size may have made it difficult to observe statistically significant results. Thus, we also examined the pattern of coefficients. This analysis suggested that "other" students (mostly Asians) tended to perform slightly better with "other" teachers than with white teachers, and white students tended to do better with white teachers than with teachers of another racial/ethnic group. However, having a teacher of the same race did not make a difference for Hispanic or black examinees. Hispanic students scored equally well with Hispanic and white teachers, and black students actually scored higher when their teachers were white teachers than when they were black.

Discussion

After controlling for several student and teacher background characteristics, only teaching experience showed a statistically significant correlation with student test scores. The other teacher characteristics that we measured, including racial/ethnic group, tended to be unrelated to student achievement. However, the pattern of coefficients lend some weak support to the hypothesis that white and "other" students score higher when they have teachers whose racial/ethnic group is the same as their own. In contrast, Hispanic and black examinees did not perform better when they had teachers whose racial/ethnic group was the same as their own.

Although the present study did not find a statistically significant effect of matching student and teacher racial/ethnic groups, there may be other compelling reasons for increasing the presence of minority teachers. For example, previous research has shown that teachers give higher subjective evaluations to students of the same race/ethnicity (Ehrenberg, Goldhaber, & Brewer, 1995), and students have lower rates of absenteeism when their teachers' race/ethnicity match their own (Farkas, Grobe, Sheehan, & Shuan, 1990). Minority teachers may also serve as role models for, have more favorable attitudes toward, and hold higher expectations for minority students than do white teachers. Furthermore, the finding that as a group, minority teachers are as effective as white teachers may help alleviate the concerns of some white parents about school policies that seek to hire more minority teachers.

The lack of significant relationships, particularly between many teacher qualifications and outcomes, may stem from student achievement being related to factors that we did not measure, such as the teacher's expertise in mathematics and reading (see Ferguson, 1991). Although the study included a rough proxy for mathematical proficiency (namely, the number of math courses taken), more refined measures, such as scores on a teacher certification test, may be needed.

Study Limitations

There are several caveats that need to be considered when interpreting the results of this study. First, the teachers and students who participated in this study are not representative of others in the state. Consequently, the relationships (or lack thereof) that

were found in this research cannot be generalized beyond our sample of students, teachers, and schools.

Our study is also limited by the small numbers of minority teachers. Fewer than 100 teachers in our sample are black, Hispanic, or “other.” Moreover, additional research needs to be conducted in subject areas other than math. Minority teachers, particularly Hispanic teachers, may be more effective in other contexts, such as language or reading.

Finally, because we did not use an experimental design, we cannot be certain how self-selection effects influence the results. It is possible, for example, that minority teachers are more likely to be assigned to schools with a large minority student enrollment. We attempted to control for this effect by exploring models that took into account the percent minorities within a school. The results remained unchanged. However, our present data do not allow us to account for other kinds of self-selection effects. More studies are needed to determine how self-selection effects can modify our interpretations.
