APPENDIX B

District Theory of Action

Figure B.1 is a reproduction of PPS’s TOA illustration.
Figure B.1
Pittsburgh Public Schools Theory of Action

EXCELLENCE and EQUITY for ALL
Our Theory of Action

Promise-Readiness

Our Priorities:
Effective Teachers

- Improved Leadership
- Standardized Measures
- Ignition of Passions
- Culturally-relevant Pedagogy

Principal Effectiveness

- Pittsburgh Urban Leadership System of Excellence (PULS-E)
  - Principal Leadership Development
  - Administrative Induction Program
  - Leadership Academy
  - Assistant Superintendent Support
  - Performance-Based Evaluation
  - Performance-Based Compensation
  - Leadership for Racial Equity

Instructional Effectiveness

- Early Childhood Education
  - Repositioning
  - Rigorous Curriculum
  - Aligned Assessments
  - Response to Intervention (RtI)
  - Career & Technical Education (CTE)
  - Extended Time for Learning
  - Culturally-relevant Programming

Central Office Effectiveness

- Human Resources (HR)
- Information Technology (IT)
- District Leadership Teams
- Budget, Finance and Operations
- Student Services
- Communications

Environments that Support Teaching & Learning

- Family Community Engagement
- Safe & Welcoming Schools
- Equity as a Value
- Positive Behaviors & Habits
- Exploring Ambitions & Dreams
- Cultural Proficiency

INCREASING ACHIEVEMENT FOR ALL STUDENTS
DECREASING RACIAL DISPARITIES

The Pathway to the Promise

NOTE: The survey item read, “How much did each of the following experiences from this school year (including summer) contribute to your professional growth as a principal?” Responses are sorted in descending order by percentage responding “a large amount” in year 4. Percentages exclude principals who indicated that the item was not applicable. The table presents linked principal data from years 2, 3, and 4. Some items were not asked in all years. Percentages may not sum to 100 because of rounding. N may vary across items due to missing responses. None of the differences between year 2 and year 4 responses is statistically significant (p < 0.05); these paired t-tests were performed on the mean difference in the item scale scores rather than the difference between the percentages marking strongly disagree/disagree and strongly agree/agree. Items with N less than 10 are omitted.

NOTE: N ranged from 32 to 54. * = p-value < 0.10. ** = p-value < 0.05.
We have examined the variation in three measures of achievement growth for principals of schools that include at least some of the grades 3–8. One is the SPI-2 regular that is currently used for the PPPIP bonus awards. The other is a version of the SPI-2 that adjusts for the statewide distribution of scores in each grade and year. A similar adjustment is being done prior to calculating teacher VAMs for the PPS effective teaching initiative. The third is similar to the second but also adjusts for the average prior score in the school. This adjustment reduces the negative correlation between the performance measure and the average prior score. We have decomposed the variation of each measure into the portion due to sampling error and two other components. These other components measure the variation between principals in the district and the variation within each principal over time. The three components can be used to calculate measures of reliability and stability for the achievement growth measure (McCaffrey et al., 2009).

Defining Reliability, Stability, and Persistence

Our application of the McCaffrey et al. model begins by estimating the value that a principal adds to a school each year by the average student-level percentage achievement growth in his or her school in that year. The average student-level achievement growth for each principal can be estimated using a regression that includes an indicator variable for each principal in each year:

$$\Delta A_{it} = \delta_{kt} + \phi_{it},$$

where $\Delta A_{it}$ is the percentage achievement growth for student $i$ in year $t$, $\delta_{kt}$ is an indicator variable for principal $k$ in year $t$, and $\phi_{it}$ is an error term.

We then decompose the estimated achievement growth measure for each principal in each year into three components:

$$\bar{\delta}_{kt} = \theta_k + \xi_{kt} + \epsilon_{kt},$$

The first component, $\theta_k$, is the stable portion that is constant for the principal from year to year. The next component, $\xi_{kt}$, is the component specific to the principal that changes over time. The final component, $\epsilon_{kt}$, is the component that is due to sampling error. We assume that $\theta_k$ has a variance of $\tau^2$ in the population, that $\xi_{kt}$ has a variance of $\nu^2$ in the population, and that $\epsilon_{kt}$ has a variance of $\sigma^2$. 
\[ \frac{\sigma^2}{n} \]

in the population, where \( \sigma^2 \) is the variance of the student error term, \( \phi_i \), and \( n \) is the number of students used in the calculation of the principal’s achievement growth. The variance components are estimated using maximum likelihood under the assumption that all the components have a normal distribution.

We calculate the reliability of the achievement growth measure as the portion of the total variance of the principal effects that is not due to sampling error. This is the same as the proportion of the total variance that is due to signal rather than noise:

\[
\text{reliability} = \frac{\left( \tau^2 + \nu^2 \right)}{\left( \tau^2 + \nu^2 + \frac{\sigma^2}{n} \right)}.
\]

We define stability as the portion of the variation that is due to the stable component of the principal’s measure:

\[
\text{stability} = \frac{\tau^2}{\left( \tau^2 + \nu^2 + \frac{\sigma^2}{n} \right)},
\]

which McCaffrey et al. shows is equal to the covariance of a principal’s achievement measure from one year to the next.

Persistence is defined as the ratio of stability to reliability:

\[
\text{persistence} = \frac{\tau^2}{\left( \tau^2 + \nu^2 \right)},
\]

which is the proportion of the annual signal variance due to the stable component.

### Three Achievement Growth Measures

**SPI-2 Regular**

The currently used measure sets \( \Delta A_i \) to the percentage increase in the math and reading PSSA scaled scores for all qualifying students. Qualifying students are those who took the PSSA while enrolled in PPS in the current school year and the prior school year. Furthermore, they must be in the same school on the test date in the current school year as they were on the first “blue day” of the year (i.e., the first date for which the district reports membership to the state). The average percentage growth using this measure is 2.56 percent for the 47 schools for which we have four years of data.
SPI-2 State Adjusted

This version of the achievement growth measure accounts for statewide variation of scaled scores by subject, year, and grade. Each student’s scaled score is converted to a z-score by subtracting the average and dividing by the standard deviation where these statistics are for all students in the same year and grade throughout the state. After adjusting for state performance, each z-score is then converted back to a common scaled score distribution by multiplying by 220 and adding 1,400. The adjusted scaled scores are then used to calculate the percentage growth for each student.

Variation in the statewide distribution is thought to be due to several factors. First, actual performance can differ by grade, by subject, and over time. Scores have been increasing over time, which could reflect actual increases in knowledge of successive cohorts of students. It also could reflect, as least in part, increased “teaching to the test” by teachers throughout the state. Variation also could reflect unintentional differences in the difficulty of tests in certain grades, years, or subjects, which could lead to spurious variation in the measure over time for each principal. The average percentage growth using this measure is 0.33 percent. Rather than a measure of absolute growth, this should be interpreted as the amount by which qualifying PPS students exceeded statewide growth.

SPI-2 State and School Adjusted

This version of the measure takes the SPI-2 State Adjusted achievement growth for each student and regresses this on the student’s prior-year state-adjusted score and on the average state-adjusted score for all qualifying students in the student’s school. We then take the average residual from this regression for each school in each year as the measure of the performance of the principal.

We find a negative relationship between student achievement growth and the student’s own prior score, as would be expected because of regression to the mean. However, we find a positive relationship between growth and the average prior score in the student’s school. This could reflect a greater difficulty in producing achievement growth in schools with high concentrations of low-achieving students, or it could reflect a tendency for low-performing principals to be in schools with low average achievement. Implementing an adjustment for school-average prior scores is based on a presumption that the former explanation is more responsible for the relationship than the latter, and it raises the estimated principal effect in schools with high concentrations of previously low-achieving students relative to principals in other schools. This measure is based on one that is currently being used by the Gates-funded Measuring Effective Teaching project.

Table F.1 provides the reliability, stability, and persistence for each principal in the district. We attribute achievement growth to a principal if he or she were the only principal in the school during the year. Therefore, we eliminate the principals who were in a school only a portion of the year or who were co-principals.

The reliability measures are very high, reflecting the large number of qualifying students per school per year. On average, there were approximately 340 qualifying students contributing to the estimate of each principal effect each year, which implies that the contribution of sampling error is small.

Correcting for the statewide distribution of scores leads to a somewhat greater variation in achievement growth within schools. This increases the sampling error and decreases the portion of the total variance attributable to the combined signal of the stable and time-varying
Improving School Leadership Through Support, Evaluation, and Incentives

components of the principal effect. By way of interpretation, McCaffrey et al. shows that a stability of 0.30 implies that principals who are ranked in the top 20 percent of principals in a given year have the following probabilities of being in quintiles 1 through 5 (from top to bottom) in the following year: 0.32, 0.24, 0.19, 0.15, and 0.10. Using Figure A.1 in McCaffrey et al., we estimate that the stability of 0.21 for the SPI-2 regular implies that of principals who are ranked in the top quintile in one year, approximately 29 percent, 23 percent, 20 percent, 17 percent, and 13 percent will be in the first, second, third, fourth, and fifth quintiles, respectively, in the following year.

Correcting for the average prior score within each school each year has little additional effect on the reliability, stability, or persistence. However, it will change the values of the measures for individual principals, leading to higher values for principals at schools with large concentrations of low-achieving students at the beginning of the year.

Decomposing by School Rather Than by Principal

The analysis in the previous section is based on the presumption that it is the principal rather than the school that has a stable component to the estimated annual effects for each school. Alternatively, we could decompose the variance of the estimated effects assuming that there is a stable component for each school, rather than each principal. Table F.2 shows the result of a decomposition by school. The reliability does not change from that shown in Table F.1 because the sampling error is the same for the estimated annual effects. However, we find that the variation of the persistent component is much lower for schools than it was for principals. This suggests that, when a principal leaves a school, the achievement growth at the school changes much more than it does when the principal remains at the school.

In sum, we find that the performance of a school in a given year appears to be associated with the principal because we find greater stability and persistence in performance measures during periods with the same principal than when we ignore principal mobility. We find that

stability increases substantially when we adjust scores for the statewide distribution. We do not find that adjusting prior average student achievement in the school improves the stability or persistence, although it will attribute greater performance to principals in previously low-achieving schools.
